

# Plant Disease Detection Using Deep Learning and Convolutional Neural Networks

Presented By:  
**YASWANTH(B23227)**  
**KRISHNA(B23128)**  
**RISHI(B23156)**

# Problem Statement

Plant diseases reduce crop yield and affect food security

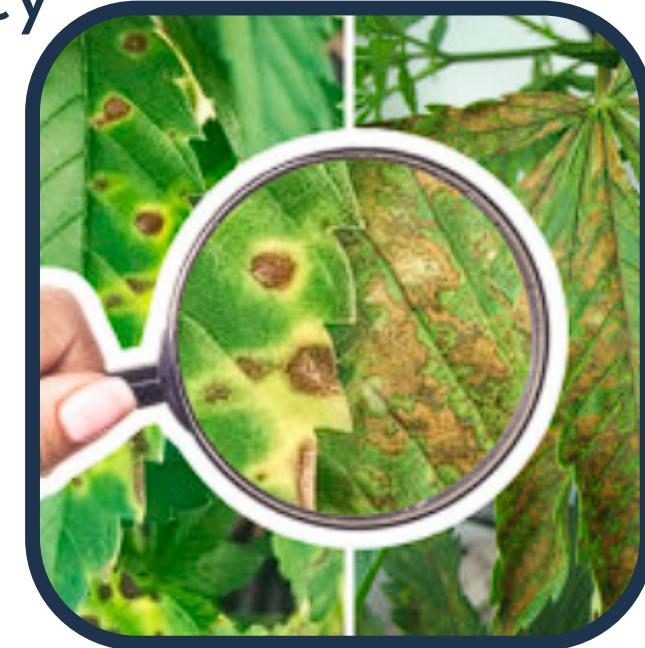

Farmers usually detect diseases manually, but:

- Manual inspection is slow
- Requires expert knowledge
- Not scalable for large farms

## GOAL :

Build a deep learning model to automatically classify plant leaf images as healthy or diseased, and to identify the disease type.

We have taken Dataset from Kaggle , which contains leaf images from different crop species and many diseases.

# Data Preprocessing

## Dataset Overview

- Total images: ~54,000
- Number of classes: 38
- Dataset was highly imbalanced, with some classes having many more samples than others

## Image Quality Cleaning :

- Blurry images removed using Laplacian variance thresholding
- Dark / underexposed images removed based on average brightness
- Duplicate images removed using perceptual hashing(pHash)

# Data Preprocessing

## Class-wise Organization & Balancing :

- Cleaned images grouped into their respective 38 plant disease categories
- Class imbalance checked and verified

## Dataset Splitting

Final cleaned dataset divided into :

- 70% Train
- 20% Test
- 10% Validation

## Image Transformations (for CNN Input)

Resize all images to  $128 \times 128$

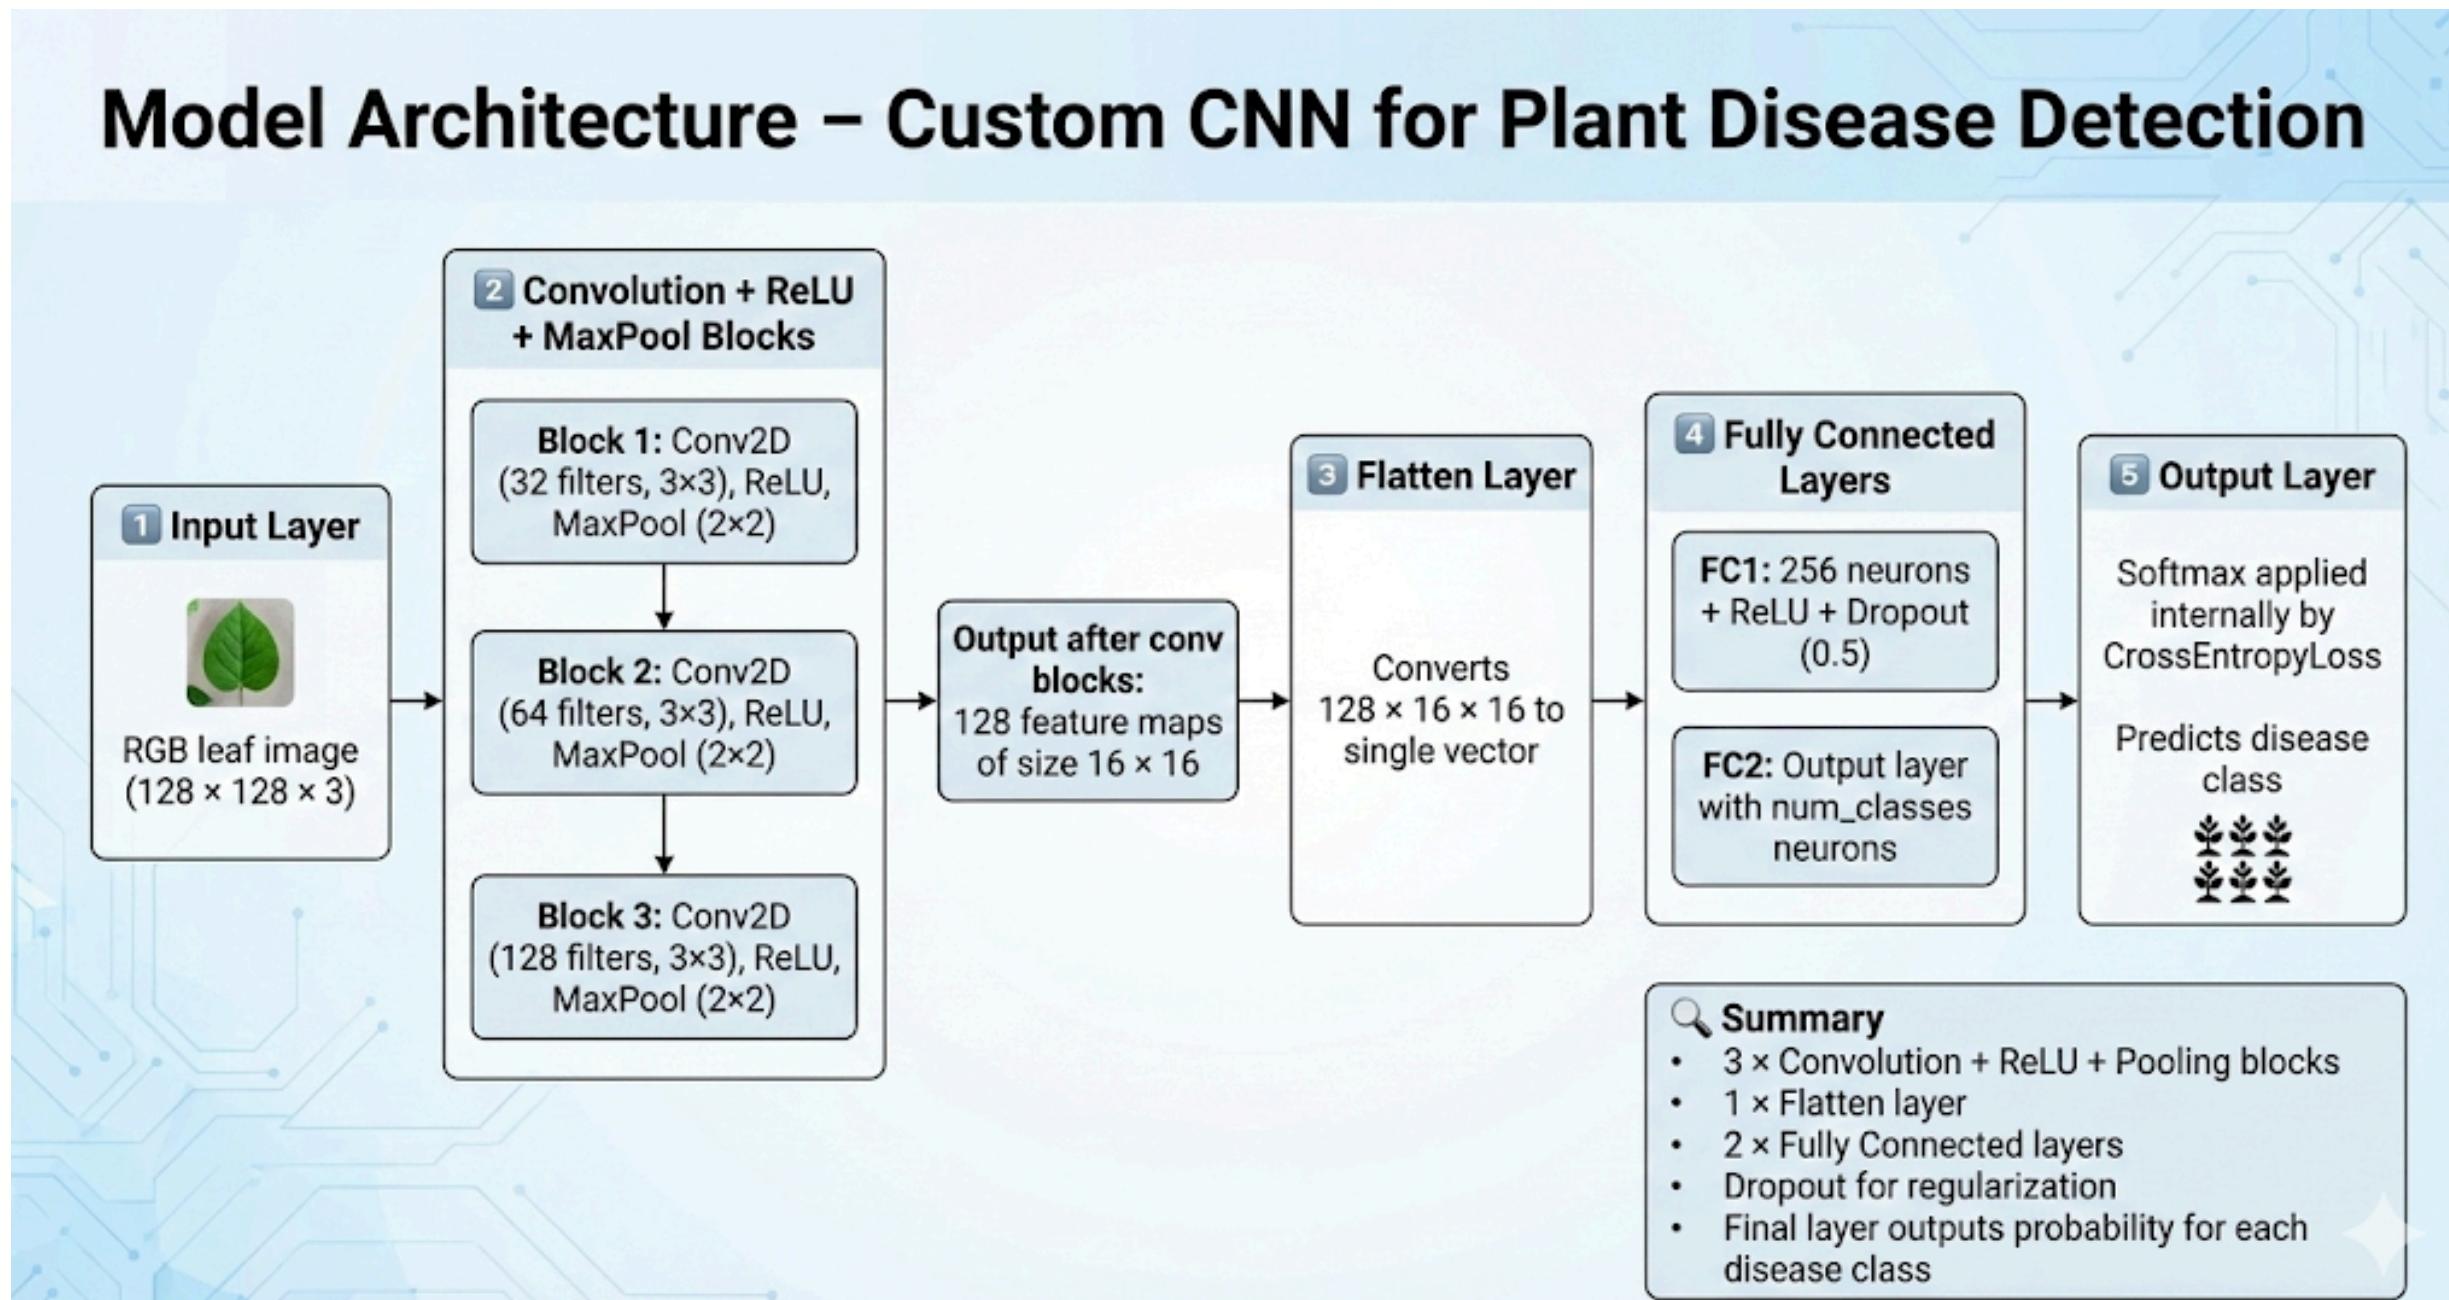

● Training data

● Validation data

● Test data

# Model Architecture

# Model Architecture

## CNN Layers

Conv1: Conv2D (32 filters,  $3 \times 3$ ) → ReLU → MaxPool( $2 \times 2$ )

Conv2: Conv2D (64 filters,  $3 \times 3$ ) → ReLU → MaxPool( $2 \times 2$ )

Conv3: Conv2D (128 filters,  $3 \times 3$ ) → ReLU → MaxPool( $2 \times 2$ )

→ Output after Conv3: 128 feature maps of size  $16 \times 16$

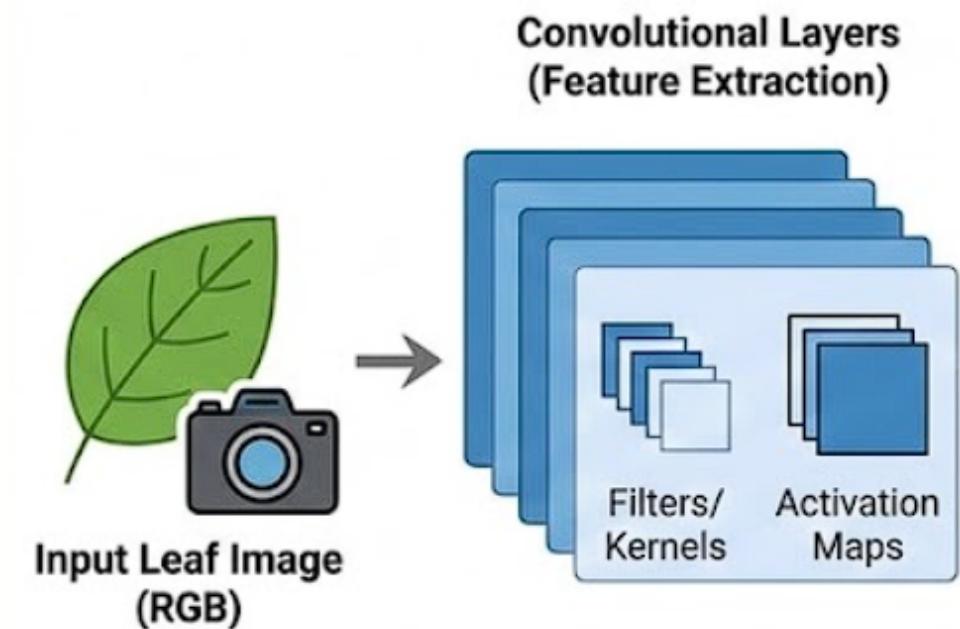

Conv1: Picks up **simple textures** on the leaf surface.

Conv2: Detects **spots, lines, and combinations of shapes**.

Conv3: Learns **complex disease patterns** (e.g., specific lesion shapes)

## Flattening for FC layer

- FC layers take 1D vector per image
- Flatten  $128 \times 16 \times 16 \rightarrow 32768$  features
- Then fc1 reduces it to 256 neurons, which capture **high-level patterns**

# Model Architecture

## Fully Connected Layers

FC1: 256 neurons + ReLU + Dropout (0.5)

FC2: Output layer with *num\_classes* neurons

## Output Layer

Softmax is applied internally by **CrossEntropyLoss**.

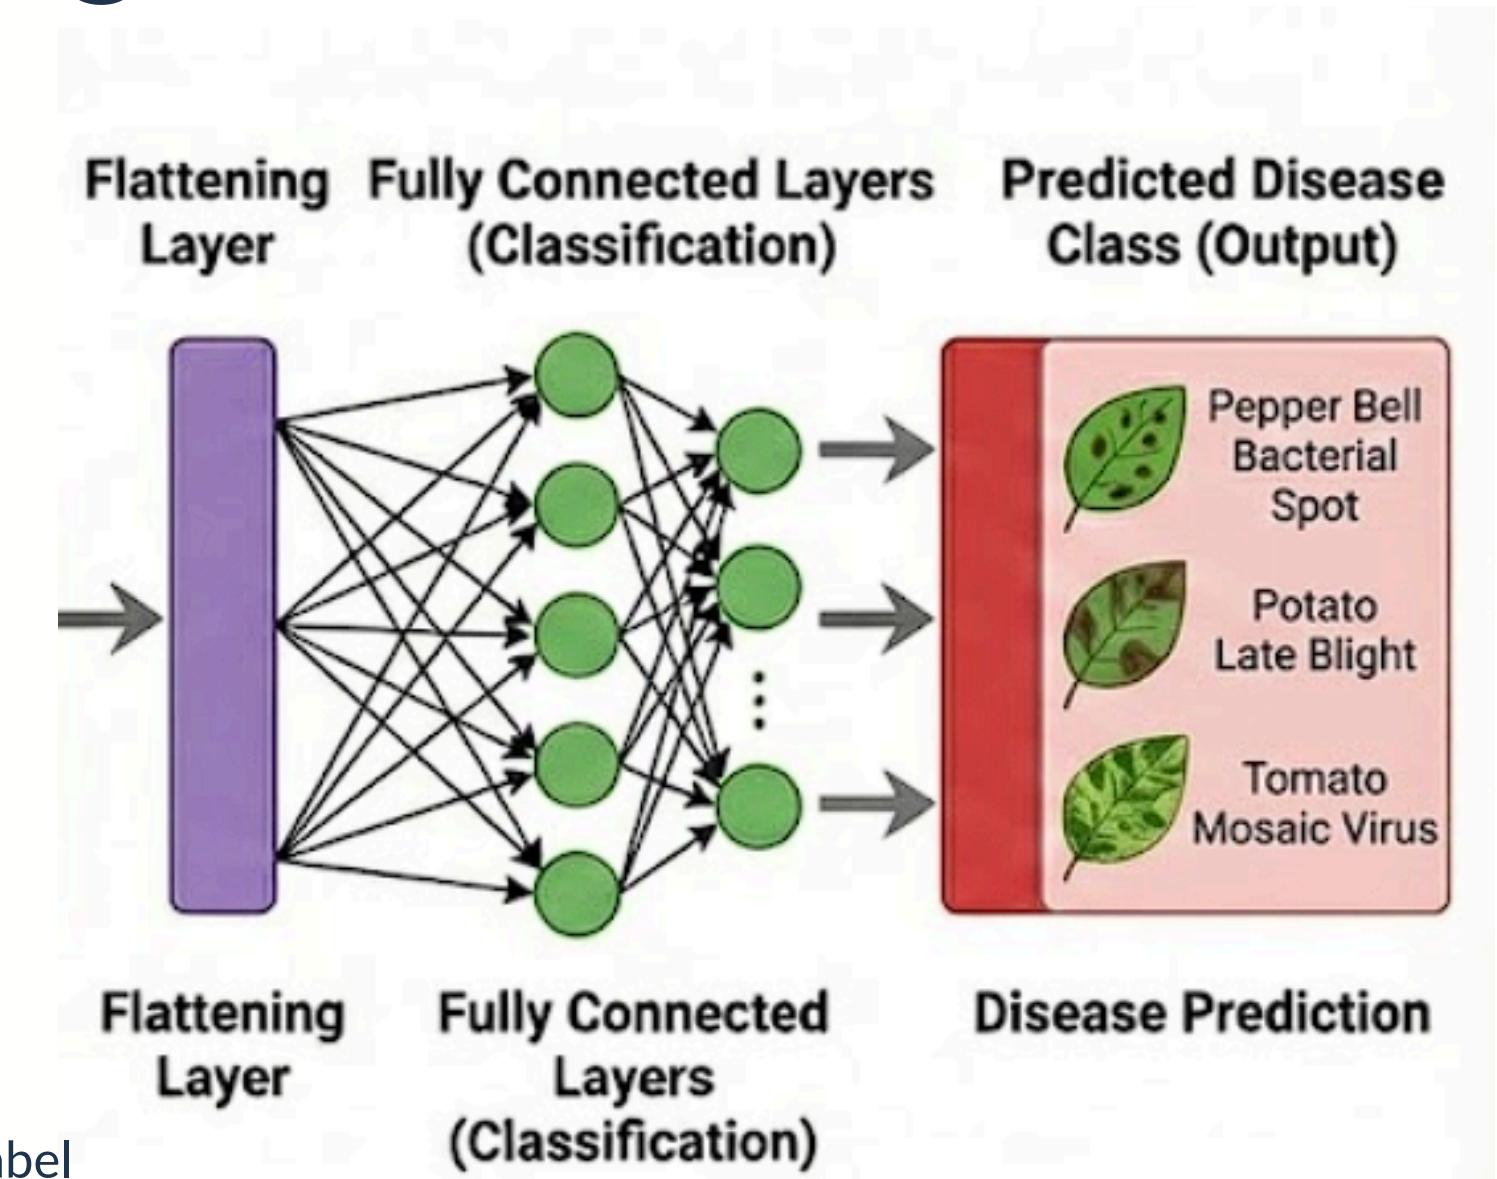

The network predicts the **disease class**.

## LOSS FUNCTION :

### Categorical Cross-Entropy Loss :

It measures how far the predicted class probabilities are from the true label

$$L = - \sum_{i=1}^C y_i \log(\hat{y}_i)$$

# Model Architecture

## Parameter Update Mechanism

- Forward pass computes predictions
- Loss is calculated
- Backpropagation computes gradients
- Adam optimizer updates weights using:

$$W = W - \eta \cdot \text{gradient}$$

where  $\eta$  = learning rate

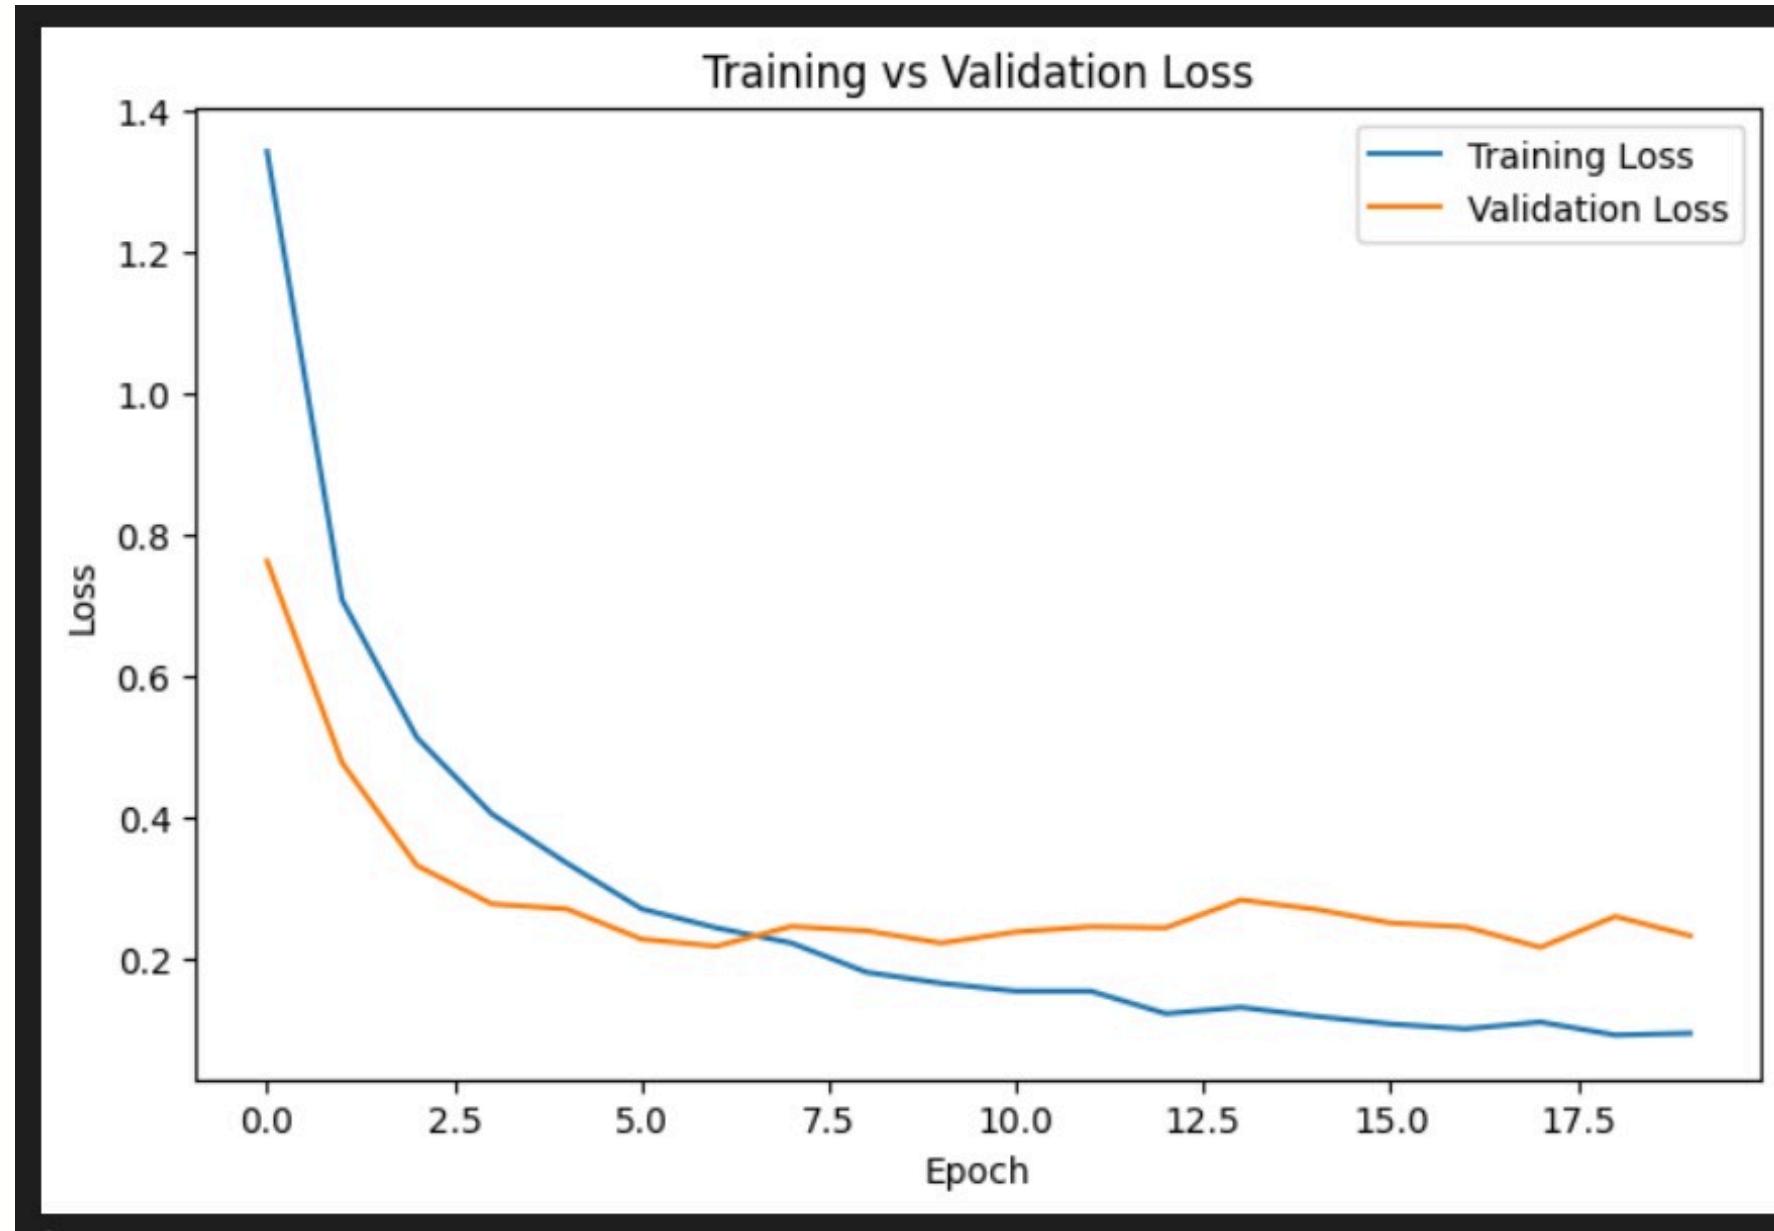

# Results :

**Result : Unknown image**

Testing with Real leaf from college :

**Result :**  
**LEAF WITH**  
**NO**  
**DISEASE**

<b>MEMEBER</b>	<b>CONTRIBUTION</b>
Rishi	Managed dataset collection and preprocessing, including removing blurry, dark, and duplicate images.
Yashwanth	Designed and implemented the CNN model, trained and optimized it for best performance.
Krishna	Evaluated model behavior (checked for overfitting), analyzed training/validation accuracy trends, and determined suitable number of epochs.

# Thank You
